

Whit Electric Driven Cars

(!):All components bellow are simply samples, and final components with a higher visual quality and beauty can and will be used as per request prior to assembly by customer/consumer().

(!) Electric Motor hypothesis: With four electric motors at a rated rpm of 10 thousand Rpm each, and each rpm generates a forward wheel movement of 60 cm forward, with a simple calculation of 10 thousand rpm x four electric motors = 40 thousand total Rpm x 60 cm wheel movement forward = 2.4 million cm forward per minute / 100 = 24 thousand meters wheel forward per minute / 1000 = 24 kilometres wheel forward per minute x 60 = 1440 kilometres per hour maximum hypothetical speed on a dyno benchmark test.

Due to weight of vehicle and traction and grip, maximum speed will be expected slower.

Expected realistic maximum/top speed is roughly between 400 kilometres per hour to 600 kilometres per hour depending upon grip, traction and Weight.

Electric wheel module. 1. Wheels, 2. Hub motor, 3. Steering knuckles, 4. Shock absorber connectors, 5. Spring damping shock absorber, 6. Pusher connection, 7. Electric actuator, 8. Lower control arm

We can steer a ground moving vehicle with ease simply via the use of dual compact electric motors attached to the wheel units attachment point to the lower control arm, as can be seen on the image example above marked/numvered 3. The dual motors are mounted precisely at the number three marker, with one motor spinning clockwise while the other electric motor spins anticlockwise. As we steer, with simple if do commands, we enable the vehicle to steer properly, as we steer left or right, the dual electric motors activates/turns on, physically turning the wheel left or right.

The red section of the example image above, numbered/marked as 2 is the main electric motor of an electric car, the electric motor that moves the car forward and backward. It's best and simplest to mount the drive electric motor directly to the vehicle's wheels. A dual electric motor per wheel is required to achieve reverse functions or a dedicated single motor system with the front wheels electric motors spinning clockwise for forward acceleration while the rear wheels

electric motors spin anti clockwise for reverse acceleration, as to say reverse. If a dual electric motor mechanism is used, all four wheels can both spin clockwise and anti clockwise, as to say, a four wheel driven vehicle that drives four wheels forward and four wheel reverse or the other mechanism where you have a frontal two wheel drive and a rear two wheel drive for reverse. Both mechanisms and methods functions greatly and it's up to the individual to pick and choose which one they desire, there are no major performance differences. Ignore all the nonsense talk about rear wheel drive being better than front wheel drive, all the same.

By the way, the methods listed above do not require a physical transmission, as its purely electric motors activates driven directly at the wheel, and to engage reverse and forward drive, we simply just push a button, a physical button or a digital button.

How to connect an electric motor to a car wheel and to the main frame of a car?

Simply attach a break disk circle to the center rod of the electric motor and break calipers to the break disks, make sure the break calipers back plate is attached to the electric motor case/ housing, and further mount a wheel with tires on to the break disks attached to the electric motors center rod.

With this simple steps, you should have achieved a functional wheel base for a ground vehicle.

its a electrical car build below, however, we could add speakers for exhaust sounds via a audio file that is programmed to play based on the gas pedal pushed down percentage and ignition button for start up sound, it sounds just the same as the combustion engine variant, you could never tell its a electrial, a Ev with that Rev Whine.

How to attach the lower control arm to the vehicle shell/chassi/frams? We can simple use a drill machine to drill some bolt holes onto the frame/shell/chassi and bolt on a rod with lug nut closer and use the lug nut tightening device to keep the lug nuts titanium tight. Don't forget to slide the lower control arm onto the rod so the arm can move upwards and downwards freely and then bolt on the rod onto the chassi/shell/chassi.

(!)All sample components can be switched and swapped with equivalent components based on custom desire and design, from the car chassi frame to the exhaust sound files, everything and anything in general.

(S.5) ECU with soldered away WiFi/internet and bluetooth connectivity. Plug all Electric motors and caliper electric motors and all other electrical components to the usb relay switches, and the relay switches to the mini pc/ecu via soldered usb cable connection. And connect all the relay switches to the car battery) with USB extension unit to allow unlimited usb plugged in with coms

label. All called and defined integers of relays are manually labelled to correct usb coms.

(!The Ecu must have its Bios flashed to a Bios that powers on the Ecu/Mini as soon as the Ecu/Mini Pc is connected to power/electric power/curent, with no manual turn on required. It's best to connect the Edu directly with the vehicles main charging port power inlet and with the vehicle's battery outlet at the same time. The Ecu software must be installed to run at start up after boot, and perhaps should be installed to always run in the background and use a always running software and if a software crash happens, automatically restore.)

(!) In order to create a functional software, use a syntax/code emulator to create a runnable application such as python and a .py code file. Make sure to import .pygame for the components broadcasted outputs such as steering wheel axis and foot pedal controls to be fetched successfully into the software. Also create all the integers found in the source code below, best to use an AI code compiler such as ChatGPT, or Vos inbuilt compiler or Github inbuilt compiler. Also make sure to source your desired sound files listed below in the source code, such as

exhaust sound files. And lastly, correctly create the USB coms integers and add the syntax that outputs data to said usb coms integers. (!) Copy and Paste the source code below into the code compiler. Use an Ai compiler to automatically import .pygame and create the required integers.

Software Syntax:

#!All (x) integers below must be specified and defined to the correct values after a complete vehicle is assembled and fine tuned.

#!x pedal pushed down rate corresponded to x electric flow)

#!Relay control: relay on/off == relay true/false)

Airbags:

If Body Crash sensor True

Activate Airbag true

Else

Activate Airbag false

We need a adapter that plugs into the Airbag wires and at the other end a usb cable, via the usb cable, the ecu can send a Crash True value and activate the Airbags. Our crash detector is two loose copper wires attached with a tiny space between right behind the front bumper and rear bumper and side skirts, if the frame of the vehicle is hit hard and bends inwards softly, the two loose wires touch each other and a electrial continoution happens, sending a pulse to a arduno like board which sends a pulse true value to the the Ecu, if crash pulse value true, crash true, if crash true, airbags true
